#### **Lecture 10: Reference Generation**

[IFAC PB Ch 7, Ch 9 p. 68-72, these slides]

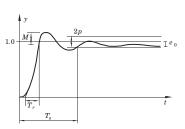

- Input-output approach
- State-space approach
- Nonlinear reference generation

#### **The Servo Problem**

How to make the output respond to command signal changes in the desired way

Typical design criteria:

- Rise time, T<sub>r</sub>
- Overshoot, M
- Settling time, Ts
- Steady-state error,  $e_0$
- ..

Simplistic Setpoint Handling – Error Feedback

#### Problems:

- Step changes in the setpoint can introduce very large control signals
- ullet The same controller C(z) must be tuned to handle both disturbances and setpoint changes
  - No separation between the regulator problem and the servo problem

#### **Common Quick Fixes**

• Filter the setpoint signal

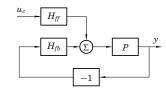

• Rate-limit the setpoint signal

- · Introduce setpoint weighting in the controller
  - E.g. PID controller with setpoint weightings  $\beta$  and  $\gamma$

**A More General Solution** 

Use a two-degree-of-freedom (2-DOF) controller, e.g.:

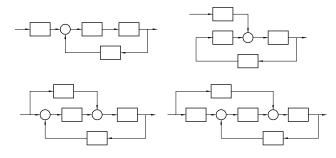

## Design procedure:

- 1. Design feedback controller  $H_{fb}$  to get good regulation properties (attenuation of load disturbances and measurement noise)
- 2. Design feedforward compensator  ${\cal H}_{\!f\!f}$  to obtain the desired servo performance

Separation of concerns

**2-DOF Control Structures** 

A 2-DOF controller can be represented in many ways, e.g.:

(For linear systems, all these structures are equivalent)

## **Example: PID with Setpoint Weighting**

$$\begin{split} u &= K \left(\beta y_{sp} - y + \frac{1}{T_I} \int (y_{sp} - y) d\tau + T_D \frac{d}{dt} (\gamma y_{sp} - y)\right) \\ &= K \left(e + \frac{1}{T_I} \int e \, d\tau + T_D \frac{de}{dt}\right) \\ &+ \underbrace{K(\beta - 1)}_{K_1} y_{sp} + \underbrace{T_D K(\gamma - 1)}_{K_2} \underbrace{\frac{dy_{sp}}{dt}} \end{split}$$

Interpretation: Error feedback + feedforward from  $y_{sp}$ 

The transfer function from  $u_c$  to y is

$$H_{yu_c} = \frac{P(H_{ff} + CH_m)}{1 + PC}$$

Choose

$$H_{ff} = \frac{H_m}{P}$$

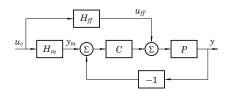

Then

$$H_{yu_c} = \frac{P(\frac{H_m}{P} + CH_m)}{1 + PC} = H_m$$

Perfect model following!

## Reference Generation - Input-Output Approach

2-DOF control structure with reference model and feedforward:

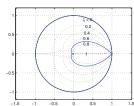

- ullet  $H_m$  model that describes the desired servo performance
- ullet  $H_{\it ff}$  feedforward generator that makes y follow  $y_m$ 
  - Goal: perfect following if there are no disturbances or model errors

#### **Restrictions on the Model**

In order for  $H_{\it ff}=\frac{H_{\it m}}{P}$  to be implementable (causal and stable),

- ullet  $H_m$  must have at least the same pole excess as P
- ullet any unstable zeros of P must also be included in  $H_m$

In practice, also poorly damped zeros of P (e.g. outside the heart-shaped region below) should be included in  ${\cal H}_m$ 

# **Example: PID Control of the Double Tank**

Process:

$$G(s) = \frac{3}{(1+60s)^2}$$

Sampled process (h = 3):

$$H(z) = \frac{0.003627(z + 0.9672)}{(z - 0.9512)^2}$$

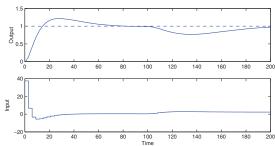

PID controller tuned for good regulation performance:

$$C(s) = K \left( 1 + \frac{1}{sT_i} + \frac{sT_d}{1 + sT_d/N} \right)$$

11

with K = 7,  $T_i = 45$ ,  $T_d = 15$ , N = 10, discretized using first-order hold.

Simulation with error feedback:

- Load disturbance at time 100 regulated as desired
- Very large control signal at time 0 and overshoot in the step response

Reference model (critically damped - should not generate any overshoot):

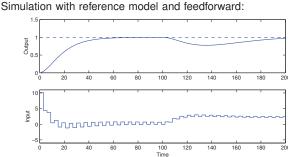

$$G_m(s) = \frac{1}{(1+10s)^2}$$

Sampled reference model

$$H_m(z) = \frac{0.036936(z + 0.8187)}{(z - 0.7408)^2}$$

Feedforward filter:

$$H_{ff}(z) = \frac{H_m(z)}{H(z)} = \frac{10.1828(z + 0.8187)(z - 0.9512)^2}{(z - 0.7408)^2(z + 0.9672)}$$

- · Perfect step response according to the model
- · Unpleasant ringing in the control signal
  - due to cancellation of poorly damped process zero; note that  $u_{ff}(k)=\frac{H_m(q)}{H(q)}u_c(k)$

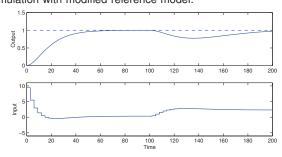

Modified reference model that includes the process zero:

$$H_m(z) = \frac{0.034147(z + 0.9672)}{(z - 0.7408)^2}$$

New feedforward filer:

$$H_{ff}(z) = \frac{H_m(z)}{H(z)} = \frac{9.414(z - 0.9512)^2}{(z - 0.7408)^2}$$

Simulation with modified reference model:

· Ringing eliminated

#### Remark

In the implementation, both  $u_{\it ff}$  and  $y_{\it m}$  can be generated by a single dynamical system:

Matlab:

>> H = ... % define process % define reference model >> Hm = ... >> refgen = [Hm/H; Hm] % concatenate systems >> minreal(ss(refgen)) % make minimal state-space realization Simplistic Setpoint Handling in State Space

Replace u(k) = -Lx(k) with

$$u(k) = L_c u_c(k) - Lx(k)$$

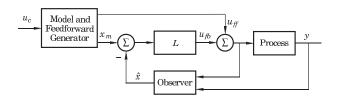

The pulse transfer function from  $u_c(k)$  to y(k) is

$$H(z) = C(zI - \Phi + \Gamma L)^{-1}\Gamma L_c = L_c rac{B(z)}{A_m(z)}$$

In order to have unit static gain (H(1) = 1),  $L_c$  should be chosen as

$$L_c = rac{1}{C(I - \Phi + \Gamma L)^{-1}\Gamma}$$

## Reference Generation - State Space Approach

The model should generate a reference trajectory  $x_m$  for the process state x (one reference signal per state variable)

The feedforward signal  $u_{\it ff}$  should make x follow  $x_{\it m}$ 

 Goal: perfect following if there are no disturbances or model errors Linear reference model:

$$x_m(k+1) = \Phi_m x_m(k) + \Gamma_m u_c(k)$$
$$y_m(k) = C_m x_m(k)$$

Control law:

$$u(k) = L(x_m(k) - \hat{x}(k)) + u_{ff}(k)$$

- How to generate model states  $x_m$  that are compatible with the real states x?
- How to generate the feedforward control  $u_{ff}$ ?

20

## **Design of the Reference Model**

Start by choosing the reference model identical to the process model, i.e.,

$$x_m(k+1) = \Phi x_m(k) + \Gamma u_{ff}(k)$$
$$y_m(k) = Cx_m(k)$$

Then modify the dynamics of the reference model as desired using state feedback ("within the model")

$$u_{ff}(k) = L_{cm}u_c(k) - L_mx_m(k)$$

Gives the reference model dynamics

$$x_m(k+1) = (\Phi - \Gamma L_m)x_m(k) + \Gamma L_{cm}u_c(k)$$
$$y_m(k) = Cx_m(k)$$

Model and Feedforward Generator  $u_{ff}$   $u_{c}$   $L_{cm}$   $\sum$  Model  $x_{m}$ 

2:

## **Design of the Reference Model**

Design choices:

- $\bullet$   $L_m$  is chosen to give the model the desired eigenvalues
- $L_{cm}$  is chosen to give the model the desired static gain (typically 1)

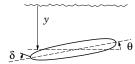

(The above model will have the same zeros as the plant. Additional zeros and poles can be added by extending the model.)

## **Complete State-Space Controller**

The complete controller, including state feedback, observer, and reference generator is given by

$$\begin{split} \hat{x}(k+1) &= \Phi \hat{x}(k) + \Gamma u(k) + K(y(k) - C\hat{x}(k)) \\ x_m(k+1) &= \Phi x_m(k) + \Gamma u_{ff}(k) \\ u(k) &= L(x_m(k) - \hat{x}(k)) + u_{ff}(k) \\ u_{ff}(k) &= -L_m x_m(k) + L_{cm} u_c(k) \end{split}$$
 (Control signal)

## **Design Example: Depth Control of Torpedo**

State vector:

$$x = \left(\begin{array}{c} q \\ \theta \\ y \end{array}\right) = \left(\begin{array}{c} \text{pitch angular velocity } \\ \text{pitch angle} \\ \text{depth} \end{array}\right)$$

Input signal:

 $u = \delta = \text{rudder angle}$ 

## **Torpedo: Continuous-Time Model**

Simple model:

$$\begin{aligned} \frac{dq}{dt} &= aq + b\delta \\ \frac{d\theta}{dt} &= q \\ \frac{dy}{dt} &= -V\theta \ (+ \ c\delta) \end{aligned}$$

where a=-2, b=-1.3, and V=5 (speed of torpedo)

$$\dot{x} = \begin{pmatrix} a & 0 & 0 \\ 1 & 0 & 0 \\ 0 & -V & 0 \end{pmatrix} x + \begin{pmatrix} b \\ 0 \\ 0 \end{pmatrix} u$$
$$y = \begin{pmatrix} 0 & 0 & 1 \end{pmatrix} x$$

26

## **Torpedo: Sampled Model**

Sample with h = 0.2

$$x(kh+h) = \begin{pmatrix} 0.67 & 0 & 0\\ 0.165 & 1 & 0\\ -0.088 & -1 & 1 \end{pmatrix} x(kh) + \begin{pmatrix} -0.214\\ -0.023\\ 0.008 \end{pmatrix} u(kh)$$

**Torpedo: State Feedback** 

- u(k) = -Lx(k)
- load disturbance rejection

Desired continuous-time dynamic behaviour:

- $\bullet$  two complex-conjugated poles with relative damping 0.5 and natural frequency  $\omega_c$
- one pole in  $-\omega_c$
- a single parameter decides the dynamics

Desired characteristic polynomial

$$(s^2 + 2 \cdot 0.5 \cdot \omega_c s + \omega_c^2)(s + \omega_c) = s^3 + 2\omega_c s^2 + 2\omega_c^2 s + \omega_c^3$$

28

Corresponds in discrete time to

$$(z^2 + a_1 z + a_2) (z - e^{-\omega_c h})$$

where 
$$a_1=-2e^{-\zeta\omega_c h}\cos\left(\sqrt{1-\zeta^2}\,\omega_c h\right)$$
,  $a_2=e^{-2\zeta\omega_c h}$  with  $\zeta=0.5$ 

## **Torpedo: State Feedback in Matlab**

Matlab code

29

## **Torpedo: Observer Design**

- $\hat{x}(k+1) = \Phi \hat{x}(k) + \Gamma u(k) + K(y(k) C\hat{x}(k))$
- measurement noise rejection + state estimation

Observer Dynamics:

- the same pole layout as in the control design
- ullet parametrized by  $\omega_o$  instead of  $\omega_c$
- ullet typically faster dynamics than the controller, e.g.,  $\omega_o=2\omega_c$

Desired continuous-time characteristic polynomial:

$$(s + \omega_o)(s^2 + \omega_o s + \omega_o^2) = s^3 + 2\omega_o s^2 + 2\omega_o^2 s + \omega_o^3$$

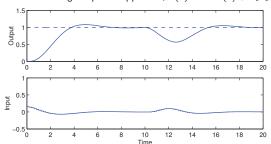

Discrete time characteristic polynomial given from previous slide

#### **Torpedo: Observer Design in Matlab**

32

# **Torpedo: Simplistic Setpoint Handling**

Simulation assuming simplistic approach,  $u(k) = -L\hat{x}(k) + L_c u_c(k)$ 

• Slow step response with overshoot

## **Torpedo: Model and Feedforward Design**

Reference model:

$$x_m(k+1) = \Phi x_m(k) + \Gamma u_{ff}(k)$$
$$y_m(k) = Cx_m(k)$$

Feedforward:

$$u_{ff} = -L_m x_m + l_r r$$

Desired characteristic polynomial:

$$(s + \omega_m)^3 = s^3 + 3\omega_m s^2 + 3\omega_m^2 s + \omega_m^3$$

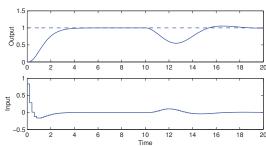

(critically damped - important!)

- ullet Parametrized using  $\omega_m$
- ullet Chosen as  $\omega_m=2\omega_c$

# Torpedo: Model and Feedforward Design in Matlab

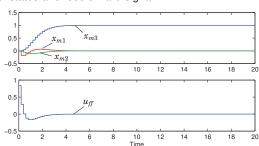

Corresponding discrete time characteristic polynomial from Matlab

## **Torpedo: Final Controller**

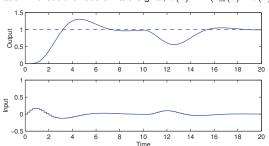

• Faster step response without overshoot

Model states and feedforward signal:

- The model states and the feedforward signal are not affected by the load disturbance
- Open loop

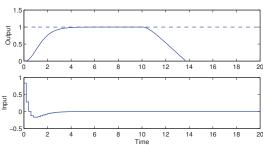

Simulation without the feedforward signal,  $u(k) = L(x_m(k) - \hat{x}(k))$ :

 Does not work very well – the feedforward term is needed to get the desired reference step response

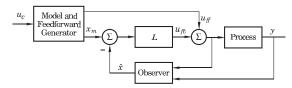

В

Simulation without the feedback term,  $u(k) = u_{ff}(k)$ :

 Does not work at all – the feedback is needed to handle the load disturbance **Nonlinear Reference Generation** 

Recall the state-space approach to reference generation:

Often,  $u_{\it ff}$  and  $x_{\it m}$  do not come from linear filters but are the result of solving an optimization problem, e.g.:

- Move a satellite to a given altitude with minimum fuel
- Position a mechanical servo in as short time as possible under a torque constraint
- Move the ball on the beam as fast as possible without losing it.

**General Solution** 

- $\bullet$  Derive the feedforward (open-loop) control signal  $u_{\it ff}$  that solves the optimization problem
  - Course in Nonlinear Control (FRTN05, Lp Vt 2)
- The model state trajectories are generated by solving

$$\frac{dx_m}{dt} = Ax_m + Bu_{ff}$$

**Example: Time-Optimal Control of Ball on Beam** 

State vector:

41

$$\begin{pmatrix} x \\ v \\ \phi \end{pmatrix} = \begin{cases} \text{ball position} \\ \text{ball velocity} \\ \text{beam angle} \end{cases}$$

Continuous-time state-space model:

$$egin{array}{l} rac{dx}{dt} = v \ rac{dv}{dt} = -k_v \phi & (k_v pprox 10) \ rac{d\phi}{dt} = k_\phi u & (k_\phi pprox 4.5) \end{array}$$

**Optimization problem:** Assume steady state. Move the ball from start position  $x(0)=x_0$  to final position  $x(t_f)=x_f$  in minimum time while respecting the control signal constraints

$$-u_{\max} \le u(t) \le u_{\max}$$

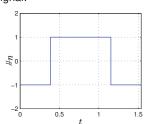

Optimal control theory gives the optimal open-loop control law

$$u_{\mathit{ff}}(t) = \begin{cases} -u_0, & 0 \leq t < T \\ u_0, & T \leq t < 3T \\ -u_0, & 3T \leq t < 4T \end{cases}$$

where

$$u_0 = \operatorname{sgn}(x_f - x_0)u_{\max}$$
 $T = \sqrt[3]{rac{|x_f - x_0|}{2k_\phi k_v u_{\max}}}$ 
 $t_f = 4T$ 

Example:  $u_{\text{max}}=1$ ,  $x_0=0$ , and  $x_f=5 \ \Rightarrow \ t_f=1.538$ Optimal control signal:

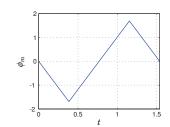

("bang-bang" control)

Solving

$$rac{d\phi_m}{dt} = k_\phi u_{ff}$$

gives the optimal beam angle trajectory

$$\phi_m(t) = \begin{cases} -k_\phi u_0 \ t, & 0 \leq t < T \\ k_\phi u_0 \ (t{-}2T), & T \leq t < 3T \\ -k_\phi u_0 \ (t{-}4T), & 3T \leq t \leq 4T \end{cases}$$

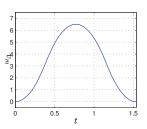

Solving

$$\frac{dv_m}{dt} = -k_n \phi_m$$

gives the optimal ball velocity trajectory

$$v_m(t) = \begin{cases} k_{\phi}k_vu_0 \ t^2/2, & 0 \le t < T \\ -k_{\phi}k_vu_0 \ (t^2/2 - 2Tt + T^2), & T \le t < 3T \\ k_{\phi}k_vu_0 \ (t^2/2 - 4Tt + 8T^2), & 3T \le t \le 4T \end{cases}$$

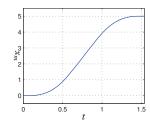

Finally, solving

$$\frac{dx_m}{dt} = v_m$$

gives the optimal ball position trajectory

$$x_m(t) = \begin{cases} x_0 + k_{\phi} k_v u_0 \ t^3/6, & 0 \le t < T \\ x_0 - k_{\phi} k_v u_0 \ (t^3/6 - Tt^2 + T^2t - T^3/3), & T \le t < 3T \\ x_0 + k_{\phi} k_v u_0 \ (t^3/6 - 2Tt^2 + 8T^2t - 26T^3/3), & 3T \le t \le 4T \end{cases}$$

Lectures 9 and 10: Summary

- Regulator problem reduce impact of load disturbances and measurement noise
  - Input–output approach: design of feedback controller  $H_{fb}(z)$ , e.g. PID controller
  - State space approach: design of state feedback and observer, including disturbance estimator
- Servo problem make the output follow the setpoint in the desired way
  - Input–output approach: design of model reference  $H_m(z)$  and feedforward filter  $H_{\it ff}(z)$
  - State space approach: design of combined reference and feedforward generator
    - \* Linear or nonlinear reference generation
