Overview of Java

Real-Time Systems, Lecture X

Martina Maggio 20 January 2016

Lund University, Department of Automatic Control

Content

[Real-Time Control System: Chapter 6.4]

- 1. Introduction
- 2. The Java Language
- 2.1 Java Statements
- 2.2 Object-Oriented Programming

Introduction

Aim of the Lecture

- Present the basic ideas and concepts behind Java.
- Show how a simple Graphical User Interface (GUI) can be implemented.

Further Sources

- Essentials of the Java programming language Part I¹ and II².
- Per Holm, Objektorienterad programmering och Java, Studentlitteratur, 1998.
- Arnold and Gosling, The Java Programming language, 4th edition³, 2005.
- Java links and material on the course home page.

Overview

- Developed at Sun Microsystems (by Gosling et al.);
- Sun acquired Oracle in 2009;
- Syntax from C and C++, semantics from Simula
- General object-oriented language;
- First release in May 1995, Latest release Java 8 in 2014;
- Java 9 scheduled for March 2017;
- Originally intended for consumer electronics;
- Later remarkted as a WWW-language;
- Programs are compiled into bytecode and interpreted by the Java Virtual Machine (JVM), platform independent.

 $[\]label{eq:linear_section} $$\frac{1}{2}$ http://www.oracle.com/technetwork/java/index-138747.html $2 http://www.oracle.com/technetwork/java/basicjava2-138746.html $3 Online from http://www-public.tem-tsp.eu/~gibson/Teaching/CSC7322/$

Applications, Applets and Servlets

- Java applications are stand-alone programs;
- Java applets run within Java-enabled browsers;
- Java servlets run within network servers.

The Java Language

- Simple: easy to learn, based on today's practice (borrow C++ syntax), small size, automatic garbage collection;
- Network-oriented: full support for networked applications, TCP/IP protocols (FTP, HTTP), open, access objects across the net;
- Portable: architecture-netural, byte code interpreter;
- (more) **Strongly typed** (than C): compile-time checks, safe references instead of unsafe pointers;
- Secure: the bytecode verifier verifies the code before it is interpreted, the security manager in the JVM check access to resources like file system and network.

7

7

11

The Java Language

Hello World

```
class HelloWorld {
   public static void main(String[] arguments) {
       System.out.println("Hello World, I print!");
   }
   Compile and execute:
```

The main method must be declared in the class that is started from the command line (with 'java classname').

\$ javac HelloWorld.java
(creates HelloWorld.class)
\$ java HelloWorld
HelloWorld, I print!

A source file may contain only one public class. The file should have the same name as the public class with the java extension. The output of the compilation is the file named as the class with the extension .class.

10

Comments

```
1 // Line comments extend to the end of the line
2
3 /* A multi-line comments,
4 that continues on multiple lines */
5
6 /** Documentation comment,
7 to be used only immediately before a class or method declaration
8 used by the javadoc tool **/
```

Simple Declarations

```
int m, n; // integer variables
double x, y; // real variables
double z = 0.89; // initialization
boolean b; // true or false
char ch; // single character
```

```
double radians;
int degrees;

degrees = radians * 180 / 3.14; // error:
// incompatible types: possible lossy conversion from double to int
degrees = (int) (radians * 180 / 3.14); // ok
```

Explicit Type Casting

```
Java Statements
    While, For and DoWhile Statements:
                                 double sum = 0.0;
                                  2 int i;
                                 3 for (i = 1; i <= 100; i++) {
   1 double sum = 0.0;
                                      sum = sum + 1.0 / i;
    double term = 1.0;
   3 int k = 1;
   4 while (term >= 0.00001) {
       sum = sum + term;
                                 double x = 0.0;
     term = term / k;
                                 double y = 20.0;
                                 3 do {
4 x = x + 1.0;
                                      y = y / x;
                                  6 } while (y > 3.0);
                                                                   16
```

```
Tava Statement:

| Switch (x) {
| Case statement: | y = 0;
| Society | y = 0;
| Case 1: y = 0;
| Society | y = 0;
| Case 2: y = 1;
| Case 2: y = 1;
| Case 3: y = 1;
| Case 3: y = 1;
| Case 3: y = 1;
| Case 4: y = 0;
| Case 5: y = 0;
| Case 6: y = 0;
| Case 7: y
```

Object-Oriented Programming

- Class: a structure that defines the data (state) and the operations (methods) that can be performed on that data (the behavior).
 Abstract data type. A class without methods corresponds to an ordinary record (Pascal) or struct (C).
- Object: an instance (or object) is an executable copy of a class.

Classes and objects provide modularity and information hiding.

Object-Oriented Programming

• Inheritance: a class inherits state and behavior from its superclass (single inheritance) or superclasses (multiple inheritance).

Subclasses can add state and behavior. Subclasses can override (redefine) inherited state and behavior. In case of single inheritance the classes form an inheritance tree (class hierarchy).

Inheritance supports **re-usability** and provides a mechanism for organizing and structuring software.

19

Object-Oriented Programming

Polymorphism: a subtype is a datatype that is related to another
datatype (the supertype) by some notion of substitutability, meaning
that program elements, typically subroutines or functions, written to
operate on elements of the supertype can also operate on elements
of the subtype. If Rectangle is a subtype of Figure, any term of
type Rectangle can be safely used in a context where a term of
type Figure is expected.

There is much more to polymorphism (for example parametric polymorphism) but in object-oriented programming polymorphism is usually *subtype polymorphism*.

20

Class: Attributes

A class declaration contains a set of attributes (fields or instance variables) and functions (methods). Attributes:

```
class Turtle {
   // attributes declaration
   private boolean penDown;
   protected int x, y;
}
```

- private cannot be accessed from outside the class
- protected can be accessed from within the class and all its subclasses but not from the outside
- public can be accessed from the outside

21

23

Class: Methods

A class declaration contains a set of attributes (fields or instance variables) and functions (methods). Methods:

```
class Turtle {
    // attributes
    protected int x, y;

// methods
    public void jumpTo (int newX, int newY) {
        x = newX; y = newY;
    }
    public int getX () { return x; }
}
```

• public means they can be accessed from outside

22

Class: Constructors

A **constructor** is a special method that has no return type and is called when an object is created. It is possible to have multiple methods with the same name and different parameter sets (often used for constructors) — as long as the signatures are different.

```
class Turtle {
    // attributes
    protected int x, y;

// constructors
    public Turtle () { x = 0; y = 0; } // no params
    public Turtle (boolean initial) { // one boolean
        if (initial) { x = 5; y = 5; }
        else { x = -5; y = -5; }

    public Turtle (int startX, int startY) { // two int
        x = startX; y = startY;
    }
}
```

Class: Example

```
class Turtle {
  protected int x, y; // attributes

// constructor
  public Turtle (int startX, int startY) {
    this.jumpTo (startX, startY);

  }

// methods
  public void jumpTo (int newX, int newY) { x = newX; y = newY; }
  public int getX () { return x; }

class Main {
  public static void main(String[] args) {
    Turtle t = new Turtle(10, 10);
    a.jumpTo(t.getX(), 5);
}

s }
```

• the object that the method belongs to can be accessed using this

Class: Static Attributes

By preceding the declaration of an attribute with static the attribute becomes a class variable, all the instances share the same copy of the class variable.

```
1 class Turtle {
       // attributes
       protected int x, y;
       static public int numTurtles = 0;
       // methods
       public Turtle (int startX, int startY) {
         x = startX; y = startY;
         numTurtles++;
10
    class Main {
11
12
      public static void main(String[] args) {
         Turtle t1 = new Turtle(9, 5); Turtle t2 = new Turtle(10, 10);
System.out.println("num = " + t1.numTurtles); // num = 2
13
14
         System.out.println("num = " + t2.numTurtles); // num = 2
16
17 }
```

Class: Static Methods

The keyword static can be used also for methods. Static methods (class methods) can only access static variables (class variables). Class methods are accessible from the class itself (in addition to from each instance of the class). An example is the Math class.

```
double x = 9.0;
double y = Math.sqrt(x); // 3.0
```

26

28

Nested Classes

A class that is defined as a member of another class is called a **nested class**. It has unlimited access to its enclosing class members, even if they are declared private. A nonstatic nested class is known as an **inner** class (the most usual form of nested classes). Inner classes can be anonymous (have no name). An inner class can only be accessed via an instance of the outer class.

```
class OuterClass {
    // attributes
    private String name;
    // methods

class InnerClass {
    // attributes
    // attributes
    // methods
    public void printName() {
        System.out.println("Attribute name of the outer class: " + name);
    }
}
```

Subclasses

A subclass extends a superclass:

```
class NinjaTurtle extends Turtle {
    // attributes
    String name;

// constructors
    public NinjaTurtle (int initX, int initY, String initName) {
        super(initX, initY); // call constructor of super class
        name = initName;
    }
}
```

Subclasses

A subclass can override methods of a superclass (not possible for static or final ones):

```
or final ones):

class Turtle {
    ...
    public Turtle(int initX, int initY);
    public void jumpTo (int newX, int newY) { x = newX; y = newY; }
}

class NinjaTurtle extends Turtle {
    String name; // attributes (+ attributes in superclass)

// constructor (+ constructors in superclass)

public NinjaTurtle (int initX, int initY, String initName) {
    super(initX, initY); name = initName;
    }

public void jumpTo (int newX, int newY) { // method overriding
    super.jumpTo(newX, newY); // it is possible to call the superclass
    System.out.println(name + " jumped to a new position");
}
```

Abstract Classes

Methods can be **abstract**. They then contain only declarations without any implementation. The method must be implemented in the the subclasses. A class with an abstract method is an abstract class and must be decleared abstract. An abstract class cannot be instantiated, but it is possible to instantiate a subclass that implements the abstract methods. Sometimes it is useful to declare a class abstract even if there is no abstract methods, to structure the hierarchy.

```
abstract class Drawable {
public abstract void draw();
```

Interfaces

A way of obtaining some of the functionality of multiple inheritance without is problems. An interface defines a set of methods. Any class may implement that interface (and a class can implement several interfaces). Reference variables may be typed either by class or by interface

- An interface may contain only methods and constant declarations.
- All methods are implicitly public and abstract.
- A class can implement several interfaces, but can extend only another class
- An interface can be used as a type name.
- Interfaces can be extended like classes. An interface can extend more than one interface.

31

```
Example
      interface Drawable {
        void draw (SimpleWindow w):
        int getWidth();
        int getHeight();
     class Rectangle implements Drawable {
        private int xSide, ySide;
        public void draw(SimpleWindow w) {
           int x = w.getX(); int y = w.getY();
12
           w.lineTo(x, y + ySide);
           \label{eq:w.lineTo} \begin{array}{lll} w.lineTo(x,\ y\ +\ ySide)\,; & //\ draw\ the\ first\ line\\ w.lineTo(x\ +\ xSide,\ y\ +\ ySide)\,; & //\ draw\ the\ second\ line \end{array}
13
                                                  // draw the third line
// close the rectangle
           w.lineTo(x + xSide, y);
15
           w.lineTo(x, y);
16
        public int getWidth() { return xSide; }
17
        public int getHeight() { return ySide; }
                                                                                                        32
```

```
Example
    interface Drawable {
      void draw (SimpleWindow w);
      int getWidth();
      int getHeight();
   class Person implements Drawable {
     private String name;
     public void draw(SimpleWindow w) {
       w.writeText(name);
     public int getWidth() {
13
       return 6 * name.lenght();
15
      public int getHeight() {
16
       return 10;
18
19
                                                                               33
```

```
Example
     interface Drawable {
      void draw (SimpleWindow w);
      int getWidth();
      int getHeight();
     // it is possible to write methods that work with every instance of
     // a Drawable, like this drawWithBorder
    void drawWithBorder (Drawable d, int x, int y SimpleWindow w) {
      w.moveTo(x, y);
      d.draw(w);
12
      int width = d.getWidth():
      int height = d.getHeight();
13
       w.moveTo(x-2, y-2);
      // do 4 calls to w.lineTo() to draw the border
                                                                                34
```

Arrays

Arrays are similar to objects, accessed using reference variables.

```
int[] someInts; // integer array
Turtle[] turtleFamily; // array of references to turtles

someInts = new int[30]; // specify size when the array is created

int i;
for (i = 0, i < someInts.lenght; i++) { // lenght is predefined
someInts[i] = i * i; // indices start at 0
}</pre>
```

Call-by-value vs. Call-by-reference

- Call-by-value: when a parameter is passed to a method, Java passes it by value. For simple types, this means that the value of the int or double is passed and the method cannot modifies the value seen by the callee.
- In case an object is passed, things are more tricky. You can see it as if the object passed was a pointer, pointing to the address in which the object is stored. The pointer cannot be changed by the method, but the content of what is pointed by it can be changed. The pointer is passed with a call-by-value but its reference can be modified. So in some sense it can be seen as the call-by-reference of C.

35

```
Example
    class Dog {
      String name
      public Dog(String name) { this.name = name; }
      public String getName() { return name; }
      public void setName(String name) { this.name = name; }
      public static void main( String[] args ){
        Dog aDog = new Dog("Max");
        foo(aDog);
10
        Boolean a = aDog.getName().equals("Fifi"); // ?
12
        Boolean b = aDog.getName().equals("Max"); // ?
13
      public static void foo(Dog parameter) {
        Boolean c = parameter.getName().equals("Fifi"); // ?
15
        Boolean d = parameter.getName().equals("Max"); // ?
16
        parameter.setName("Fifi");
17
        Boolean e = parameter.getName().equals("Fifi"); // ?
19
        Boolean f = parameter.getName().equals("Max"); // ?
20
                                                                                37
```

```
Example
     class Dog {
      String name
      public Dog(String name) { this.name = name; }
      public String getName() { return name; }
       public void setName(String name) { this.name = name; }
      public static void main( String[] args ){
        Dog aDog = new Dog("Max");
        foo(aDog);
         Boolean a = aDog.getName().equals("Fifi"); // true
12
        Boolean b = aDog.getName().equals("Max"); // false
13
      public static void foo(Dog parameter) {
15
        Boolean c = parameter.getName().equals("Fifi"); // false
        Boolean d = parameter.getName().equals("Max"); // true
16
        parameter.setName("Fifi");
17
         Boolean e = parameter.getName().equals("Fifi"); // true
19
        Boolean f = parameter.getName().equals("Max"); // false
20
                                                                                38
```

```
Example
    class Dog {
      String name;
      public Dog(String name) { this.name = name; }
      public String getName() { return name; }
      public void setName(String name) { this.name = name; }
    class Main {
      public static void main( String[] args ){
        Dog aDog = new Dog("Max");
        foo(aDog);
10
        Boolean a = aDog.getName().equals("Fifi"); // ?
12
        Boolean b = aDog.getName().equals("Max"); // ?
13
      public static void foo(Dog parameter) {
        Boolean c = parameter.getName().equals("Fifi"); // ?
16
        Boolean d = parameter.getName().equals("Max"); // ?
        parameter = new Dog("Fifi");
17
        Boolean e = parameter.getName().equals("Fifi"); // ?
19
        Boolean f = parameter.getName().equals("Max"); // ?
20
                                                                                 30
```

```
Example
      String name;
      public Dog(String name) { this.name = name; }
      public String getName() { return name; }
      public void setName(String name) { this.name = name; }
    class Main {
      public static void main( String[] args ){
        Dog aDog = new Dog("Max");
        foo(aDog);
        Boolean a = aDog.getName().equals("Fifi"); // false
11
12
        Boolean b = aDog.getName().equals("Max"); // true
13
14
      public static void foo(Dog parameter) {
        Boolean c = parameter.getName().equals("Fifi"); // false
16
        Boolean d = parameter.getName().equals("Max"); // true
        parameter = new Dog("Fifi");
17
         Boolean e = parameter.getName().equals("Fifi"); // true
19
        Boolean f = parameter.getName().equals("Max"); // false
20
                                                                                40
```

References

- References are the same as pointers in C.
- Manipulation of references is not allowed (for example adding integers).
- Compile-time checks guarantee that a reference is initialized before it is used.

Memory Allocation

For **static** memory allocation, all the memory is allocated at start-up. For **dynamic** memory allocation there are two alternatives:

- memory is allocated dynamically from the heap when needed (Pascal, Modula-2, C, C++, ...):
 - manual memory management,
 - the application explicity allocates memory when needed and deallocates it when no longer use it,
 - problem: dangling pointers, memory leaks, fragmentation;
- automatic memory management (Java):
 - $\,-\,$ runtime system or OS deallocates memory automatically,
 - garbage collection,
 - problem: takes time and may disturb the real-time application.

Java Garbage Collector

The Garbage Collector in Java:

- runs as a low-priority thread,
- it is incremental: work is divided into small pieces that are spread out during the execution,
- can be explicitly invoked using System.gc(),
- real-time garbage collectors have been developed (for example by Roger Henriksson) and are part of Sun's Real-Time Java 2.

Exceptions

Exceptions happen when error occurs. The exceptions contain information about the execution (type, state of the program). During the execution, the JVM tries to find code that handles the exception (it throws the exception to a method that can handle it - the runtime systems searchers backwords through the call stack of the method until it finds a method containint appropriate code to handle the exception - the handler has a catch for the exception — if no appropriate handler is found, the application terminates with an error).

44

43

Exceptions

Exception handling code is composed by at least a try and a catch or a try and a finally (or all three).

```
class Main {
      public static void main(String[] arguments) {
        try {
           .
// code that can throw the exception
          System.out.println("try");
        } catch (Exception e) {
          // code to handle the exception of type Exception
          System.out.println("catch");
        } finally {
           // code that is executed anyway (used for cleanup)
11
          System.out.println("finally");
12
```

45

Exceptions

The keyword throw can be used to raise an exception. A method can signal that it may throw an exception in its signature, by using throws and a list of comma-separeted types of exception.

```
class Main {
      public static void main(String[] arguments) {
          System.out.println("try");
          uselessMethod(15); // prints "I am happy"
          uselessMethod(5); // throws the exception
        } catch (Exception e) {
          e.printStackTrace(); // prints the call stack
          System.out.println("catch");
11
      public static void uselessMethod(int parameter) throws Exception {
12
        if (parameter < 10) throw new Exception("I wanted something else");</pre>
14
        else System.out.println("I am happy");
15
```

46

Exceptions

Types of exceptions:

- RuntimeException exception that occurrs within the Runtime system like division by zero, the compiler does not require that these are caught or specified.
- Checked Exceptions checked by the compiler, requires that the exception is caught or specified. For example wait() and sleep can throw an ${\tt InterruptedException}.$

It is possible to define new types of exceptions (not needed for this course).

Packages

Java code is often organized in packages. A package is a collection of related classes. Attributes with unspecified visibility get package visibility (they are public to other classes in the package and private to classes that do not belong to the package). A class that should be accessible from outside the package must be declared public. Classed declared in files without a package specification belong to a 'default' package. All files belonging to the package should be stored in the same directory (named with the name of the package).

File Rectangle.java:

```
package Drawings;
public class Rectangle {
  private double lenght, height;
  public Rectangle(double 1, double h) { lenght = 1; height = h; }
  public double getArea() { return height * lenght; }
```

Package Names

- java.xxx: standard java packages (java.awt, java.awt.event)
- javax.xxx: java extension packages (javax.swing)
- User-defined packages: globally unique names convention: reversed Internet domain name followed by local directory structure (se.lth.cs.realtime, se.lth.control.realtime)

49

Standard Packages

- java.lang: Object, Class, String, ...
- java.io: Streams, Random-Access Files
- java.applet: Applet
- java.awt: Abstract Window Toolkit
- java.util: Collections, Date, Time, ...
- java.net: Sockets, Telnet, URLs, ...

50

52

Package Access

- Explicit Naming
- Gui.CommandButton button = new Gui.CommandButton();
- Import One Class
- import Gui.CommandButton;
- 2 CommandButton button = new CommandButton();
- Import a Full Package
- import Gui.*;
- CommandButton button = new CommandButton();

Graphical Interfaces: Swing

Swing is a class package for graphical user interfaces implementation. It supports buttons, menus, scrollbars and more. All the class names begin with J (JButton, JFrame, \dots).

```
import javax.swing.*;
import java.awt.*;
```

import java.awt.*,
import java.awt.event.*;

51

Containers

Every program that presents a swing GUI contains at least one top-level swing container:

- JFrame: implements a single main window
- JDialog: implements a secondary, "pop-up" window

Intermediate containers simplify the positioning of components in the window:

- IPanel
- JScrollPane
- JTabbedPane

Atomic Components

Self-sufficient entities that present information to the user or implement some user $control^4$

- JButton a button
- JTextField editable text field
- JLabel uneditable text field
- JSlider a slider
- PlotComponent local plot class

54

⁴https://docs.oracle.com/javase/tutorial/uiswing/components/index.html

Layout Management

Controls the layout of components in an intermediate container.

- BorderLayout: composed by five areas (north, south east, west and center), default layout for every content pane;
- BoxLayout: puts components in a single row or column;
- FlowLayout: lays out components from left to right, starting new rows if necessary. default layout for JPanel;
- GridLayout: places components in a cell grid (matrix), all of the

55

Event Handling

Each user action (key press, mouse movements, mouse clicks) is considered an event. The Swing system informs the Java application about an event by creating an object of class AWTEvent. The class has several subclasses, among which:

- ActionEvent: generated when a specific event for a certain component occurs (like mouse clicks);
- TextEvent: generated when the content of a text component is changed.

56

Listeners

When an event occurs, the runtime system calles a method in a listener object. A listener is an object that implements a listener interface. For example:

- ActionListener: contains actionPerformed(ActionEvent e) and is called when an ActionEvent object is generated;
- TextListener: contains textValueChanged(TextEvent e) and is called when a TextEvent object is generated.

Several components can listen to the same event. This is achieved by calling the method addActionLinstener witht the listener object as argument.

Event Methods

All event classes contain the method <code>Object getSource()</code> that returns the source object of the event. Some event classes contain event-specific methods like:

char getKeyChar(); // Key event
int getX(); int getY(); // Mouse event

5

Setting up Event Handlers

method

The event handler class implements a listener interface:

public class MyEventHandler implements ActionListener {

One should register an instance to the event handler class as a listener upon one or more components:

1 MyEventHandler handler = new MyEventHandler(); 2 component.addActionListener(handler);

In the listener interface, one should implement the actionPerformed

public void actionPerformed(ActionEvent e) {
 // code to react to the action

Event Dispatching Thread

Event-handling code executes in a single thread to make sure that events are processed sequentially and the method handling the reaction to an event terminates before handling the next action. This single thread is called event-dispatching thread.

Rule: All the code that might affect or depend on the state of a component should be executed by the event-dispatching thread.

Execute code in the event-dispatching thread

Applications usually need to perform (non user-related) operations on the graphical user interface after it is created (for example because of initialization or because of application-related events that do not depend on the user). Swing has two methods that can be used in this case:

- invokeLater: registers code to be executed by the event-dispatching thread and terminates,
- invokeAndWait: wait until the code executes.

Swing Example

61

A periodic thread that generates a sine wave. The data is sent to a GUI that plots the sine wave using a PlotComponent. The GUI also has two sliders that allow to change frequency and amplitude of the sine wave.

- Classes: Main, Sinus (the sine wave generator, Monitor (internal class of Sinus, Opcom (the GUI).
- User Threads: main, Sinus (extends the thread class), Swing event-dispatching thread.
