

# Nonlinear Control and Servo systems

## Lecture 1

Anders Rantzer and Giacomo Como

### Course Goal

To provide students with a solid theoretical foundation of nonlinear control systems combined with a good engineering ability

You should after the course be able to

- ▶ recognize common nonlinear control problems,
- ▶ use some powerful analysis methods, and
- ▶ use some practical design methods.

### Course Material, cont.

- ▶ Handouts (Lecture notes + extra material)
- ▶ Exercises (can be download from the course home page)
- ▶ Lab PMs 1, 2 and 3
- ▶ Home page  
<http://www.control.lth.se/course/FRTN05/>
- ▶ Matlab/Simulink other simulation software  
see home page

### Exercise sessions and TAs

The exercises (28 hours) are offered twice a week;

Tue 15-17 Wed 15-17

NOTE: The exercises are held in either ordinary lecture rooms or the department laboratory on the bottom floor in the south end of the Mechanical Engineering building, **see schedule on home page.**

Jerker Nordh

Jonas Dürango

### Overview Lecture 1

- Practical information
- Course contents
- Nonlinear control phenomena
- Nonlinear differential equations

### Course Material

- ▶ Textbook
  - ▶ Glad and Ljung, *Reglerteori, flervariabla och olinjära metoder*, 2003, Studentlitteratur, ISBN 9-14-403003-7 or the English translation *Control Theory*, 2000, Taylor & Francis Ltd, ISBN 0-74-840878-9. The course covers Chapters 11-16, 18. (MPC and optimal control not covered in the other alternative textbooks.)
  - ▶ ALTERNATIVE: H. Khalil, *Nonlinear Systems* (3rd ed.), 2002, Prentice Hall, ISBN 0-13-122740-8. A good, but a bit more advanced book.
  - ▶ ALTERNATIVE (Hard to get/out of print): Slotine and Li, *Applied Nonlinear Control*, Prentice Hall, 1991. The course covers chapters 1-3 and 5, and sections 4.7-4.8, 6.2, 7.1-7.3.

### Lectures and labs

The lectures (30 hours) are given as follows:

Mon 13-15, M:D  
Wed 8-10, M:E, January 18 - February 22  
Thu 10-12 M:D **January 19**

The lectures are given in English.

The three laboratory experiments are **mandatory**.

**Sign-up lists** are posted **on the web** at least one week before the first laboratory experiment. *The lists close one day before the first session.*

The Laboratory PMs are available at the course homepage.

**Before the lab** sessions some **home assignments** have to be done. No reports after the labs.

### The Course

- ▶ 14 lectures
- ▶ 14 exercises
- ▶ 3 laboratories
- ▶ 5 hour exam: **March 7, 2012.**  
Open-book exam: Lecture notes but no old exams or exercises allowed. Next exam on April 13, 2012

- ▶ Introduction. Typical nonlinear problems and phenomena.
- ▶ Linearization. Simulation.
- ▶ Stability theory.
- ▶ Periodic solutions.
- ▶ Compensation for friction, saturation, back-lash etc.
- ▶ Optimal control.
- ▶ Nonlinear control design methods.

## Linear Systems

**Definitions:** The system  $S$  is *linear* if

$$\begin{aligned} S(\alpha u) &= \alpha S(u), & \text{scaling} \\ S(u_1 + u_2) &= S(u_1) + S(u_2), & \text{superposition} \end{aligned}$$

A system is *time-invariant* if delaying the input results in a delayed output:

$$y(t - \tau) = S(u(t - \tau))$$

## Linear models are not always enough

**Example:** Ball and beam

Linear model (acceleration along beam) :

Combine  $F = m \cdot a = m \frac{d^2 x}{dt^2}$  and  $F = mg \sin(\phi)$ :

$$\ddot{x}(t) = \frac{5g}{7} \phi(t)$$

**2 minute exercise:** Find a simple system  $\dot{x} = f(x, u)$  that is stable for a small input step but unstable for large input steps.

Common nonlinear phenomena

- ▶ Input-dependent stability
- ▶ Stable periodic solutions
- ▶ Jump resonances and subresonances

Nonlinear model structures

- ▶ Common nonlinear components
- ▶ State equations
- ▶ Feedback representation

## Linear time-invariant systems are easy to analyze

Different representations of same system/behavior

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t), & y(t) &= Cx(t), & x(0) &= 0 \\ y(t) &= g(t) \star u(t) = \int g(r)u(t-r)dr \\ Y(s) &= G(s)U(s) \end{aligned}$$

Local stability = global stability:

Eigenvalues of  $A$  (= poles of  $G(s)$ ) in left half plane

Superposition:

Enough to know step (or impulse) response

Frequency analysis possible:

Sinusoidal inputs give sinusoidal outputs

## Linear models are not enough

$$\begin{aligned} x &= \text{position (meter)} \\ \phi &= \text{angle (radians)} \\ g &= 9.81 \text{ (meter/sec}^2\text{)} \end{aligned}$$

Can the ball move 0.1 meter in 0.1 seconds?

Simple approximations give

$$\begin{aligned} x(t) &\approx \frac{50}{7} \frac{t^2}{2} \phi_0 \approx 0.04 \phi_0 \\ \phi_0 &\approx \frac{0.1}{0.04} = 2.5 \text{ radians} \end{aligned}$$

Clearly outside linear region!

Contact problem, friction, centripetal force, saturation

How fast can it be done? (Optimal control)

## Stability Can Depend on Amplitude

Valve characteristic  $f(x) = ???$

Step changes of amplitude,  $r = 0.2$ ,  $r = 1.68$ , and  $r = 1.72$

## Step Responses

$r = 0.2$

$r = 1.68$

$r = 1.72$

Stability depends on amplitude!

## Stable Periodic Solutions

**Example:** Motor with back-lash

Motor:  $G(s) = \frac{1}{s(1+5s)}$

Controller:  $K = 5$

## Relay Feedback Example

Period and amplitude of limit cycle are used for autotuning

[ patent: T Hägglund and K J Åström ]

## Jump Resonances

$u = 0.5 \sin(1.3t)$ , saturation level = 1.0

Two different initial conditions

give two different amplifications for same sinusoid!

## Stable Periodic Solutions

Output for different initial conditions:

Frequency and amplitude independent of initial conditions!

Several systems use the existence of such a phenomenon

## Jump Resonances

Response for sinusoidal depends on initial condition

Problem when doing frequency response measurement

## Jump Resonances

Measured frequency response (many-valued)

## New Frequencies

**Example:** Sinusoidal input, saturation level 1

## New Frequencies

**Example:** Mobile telephone

Effective amplifiers work in nonlinear region

Introduces spectrum leakage

Channels close to each other

Trade-off between effectivity and linearity

## When is Nonlinear Theory Needed?

- ▶ Hard to know when - **Try simple things first!**
- ▶ Regulator problem versus servo problem
- ▶ Change of working conditions (production on demand, short batches, many startups)
- ▶ Mode switches
- ▶ Nonlinear components

How to detect? Make step responses, Bode plots

- ▶ Step up/step down
- ▶ Vary amplitude
- ▶ Sweep frequency up/frequency down

## 2 minute exercise

Construct a model for a "rate limiter" using some of the previous nonlinear blocks.

## New Frequencies

**Example:** Electrical power distribution

$$THD = \text{Total Harmonic Distortion} = \frac{\sum_{k=2}^{\infty} \text{energy in tone } k}{\text{energy in tone } 1}$$

Nonlinear loads: Rectifiers, switched electronics, transformers

Important, increasing problem

Guarantee electrical quality

Standards, such as  $THD < 5\%$

## Subresonances

**Example:** Duffing's equation  $\ddot{y} + \dot{y} + y - y^3 = a \sin(\omega t)$

## Some Nonlinearities

Static – dynamic

## Nonlinear Differential Equations

Problems

- ▶ No analytic solutions
- ▶ Existence?
- ▶ Uniqueness?
- ▶ etc

## Existence Problems

**Example:** The differential equation

$$\frac{dx}{dt} = x^2, \quad x(0) = x_0$$

has solution

$$x(t) = \frac{x_0}{1 - x_0 t}, \quad 0 \leq t < \frac{1}{x_0}$$

Finite escape time

$$t_f = \frac{1}{x_0}$$

## Uniqueness Problems

**Example:** The equation  $\dot{x} = \sqrt{x}$ ,  $x(0) = 0$  has many solutions:

$$x(t) = \begin{cases} (t-C)^2/4 & t > C \\ 0 & t \leq C \end{cases}$$

Compare with water tank:

$$dh/dt = -a\sqrt{h}, \quad h : \text{height (water level)}$$

Change to backward-time: "If I see it empty, when was it full?"

## State-Space Models

- ▶ State vector  $x$
- ▶ Input vector  $u$
- ▶ Output vector  $y$

$$\text{general: } f(x, u, y, \dot{x}, \dot{u}, \dot{y}, \dots) = 0$$

$$\text{explicit: } \dot{x} = f(x, u), \quad y = h(x)$$

$$\text{affine in } u: \dot{x} = f(x) + g(x)u, \quad y = h(x)$$

$$\text{linear time-invariant: } \dot{x} = Ax + Bu, \quad y = Cx$$

## Transformation to First-Order System

Assume  $\frac{d^k y}{dt^k}$  highest derivative of  $y$

$$\text{Introduce } x = \begin{bmatrix} y & \frac{dy}{dt} & \dots & \frac{d^{k-1}y}{dt^{k-1}} \end{bmatrix}^T$$

**Example:** Pendulum

$$MR^2 \ddot{\theta} + k\dot{\theta} + MgR \sin \theta = 0$$

$$x = \begin{bmatrix} \theta & \dot{\theta} \end{bmatrix}^T \text{ gives}$$

$$\dot{x}_1 = x_2$$

$$\dot{x}_2 = -\frac{k}{MR^2}x_2 - \frac{g}{R} \sin x_1$$

## Finite Escape Time

## Existence and Uniqueness

### Theorem

Let  $\Omega_R$  denote the ball

$$\Omega_R = \{z; \|z - a\| \leq R\}$$

If  $f$  is Lipschitz-continuous:

$$\|f(z) - f(y)\| \leq K\|z - y\|, \quad \text{for all } z, y \in \Omega$$

then  $\dot{x}(t) = f(x(t))$ ,  $x(0) = a$  has a unique solution in

$$0 \leq t < R/C_R,$$

where  $C_R = \max_{\Omega_R} \|f(x)\|$

## Transformation to Autonomous System

Nonautonomous:

$$\dot{x} = f(x, t)$$

Always possible to transform to autonomous system

Introduce  $x_{n+1} = \text{time}$

$$\dot{x} = f(x, x_{n+1})$$

$$\dot{x}_{n+1} = 1$$

## A Standard Form for Analysis

Transform to the following form

## Example, Closed Loop with Friction

$\Leftrightarrow$

## Multiple Equilibria

Example: Pendulum

$$MR^2\ddot{\theta} + k\dot{\theta} + MgR \sin \theta = 0$$

Equilibria given by  $\dot{\theta} = \ddot{\theta} = 0 \Rightarrow \sin \theta = 0 \Rightarrow \theta = n\pi$

Alternatively,

$$\begin{aligned} \dot{x}_1 &= x_2 \\ \dot{x}_2 &= -\frac{k}{MR^2}x_2 - \frac{g}{R} \sin x_1 \end{aligned}$$

gives  $x_2 = 0$ ,  $\sin(x_1) = 0$ , etc

## Equilibria (=singular points)

*Put all derivatives to zero!*

General:  $f(x_0, u_0, y_0, 0, 0, 0, \dots) = 0$

Explicit:  $f(x_0, u_0) = 0$

Linear:  $Ax_0 + Bu_0 = 0$  (has analytical solution(s)!)

## Next Lecture

- ▶ Linearization
- ▶ Stability definitions
- ▶ Simulation in Matlab
